

# Computational Methods for the Design of Macromolecular Therapeutic Agents

William M. Payne, MS  
Department of Pharmaceutical Sciences  
Blue Waters Symposium: June 5<sup>th</sup> 2018

University of Nebraska  
Medical Center™

# Introduction

## What is nanomedicine?

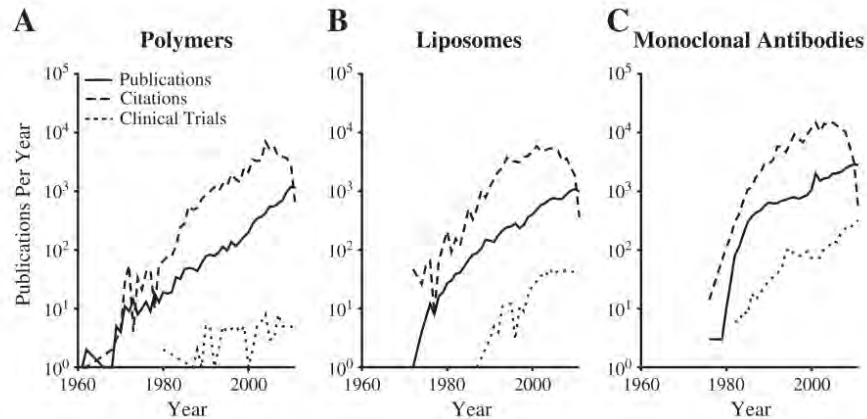

- How do we improve therapeutic efficacy as an alternate strategy?
- How is this different than traditional formulations?
- **The big question: what is a “good” nanoformulation?**

# Significance

To move the field forward, we need better formulations.

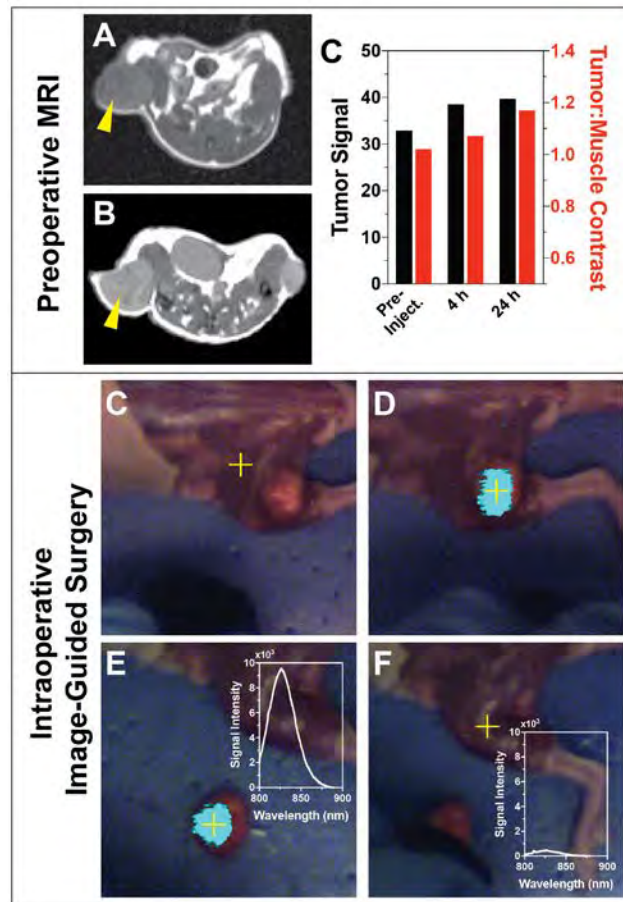

- Many nanoparticle formulations have been developed, but we do not have a way to say what is a “good” formulation.
- Developing metrics for the physical description of nanoformulations will help to invent better formulations

# Prior Work

## Context on the research

- My research during Blue Waters and for after begins with experimental observations.

# Prior Work

## More context

- Drug delivery: freely encapsulated vs. covalent modification
- Active targeting vs. passive targeting

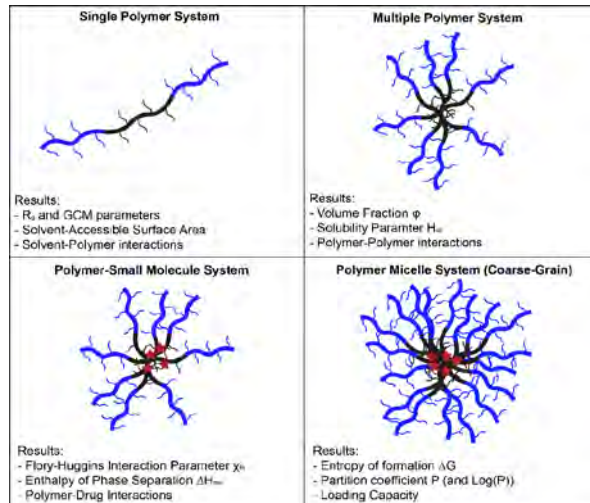

# Experimental Design

## Informing wet-lab science with theoretical insights

- I needed a way to relate simulations to experimental processes.
- Measurable interactions are key!

### Simulations of single-polymer systems

Influence of the hydrophobic fragment size on polymer dynamics

Aliphatic hydrophobic ligands

hexyl  
dodecyl  
octadecyl

Aromatic hydrophobic ligands

phenyl  
naphthyl  
pyrenyl

leads

### Simulations of multi-polymer systems

Dynamics of polymer-polymer interactions and morphology of hydrophobic domains

Octadecyl-HA (ocdHA)

Pyrenyl-HA (pyHA)

### Experiments with fluorescent dyes

Polarity and hydration of hydrophobic domains and dye-polymer interactions

Octadecyl-HA (ocdHA)

Pyrenyl-HA (pyHA)

DMAF BfDMAF  
DOAF DPAF

leads

### Simulations of dye-polymer systems

Dynamics of dye-polymer and dye-solvent interactions

Octadecyl-HA (ocdHA)

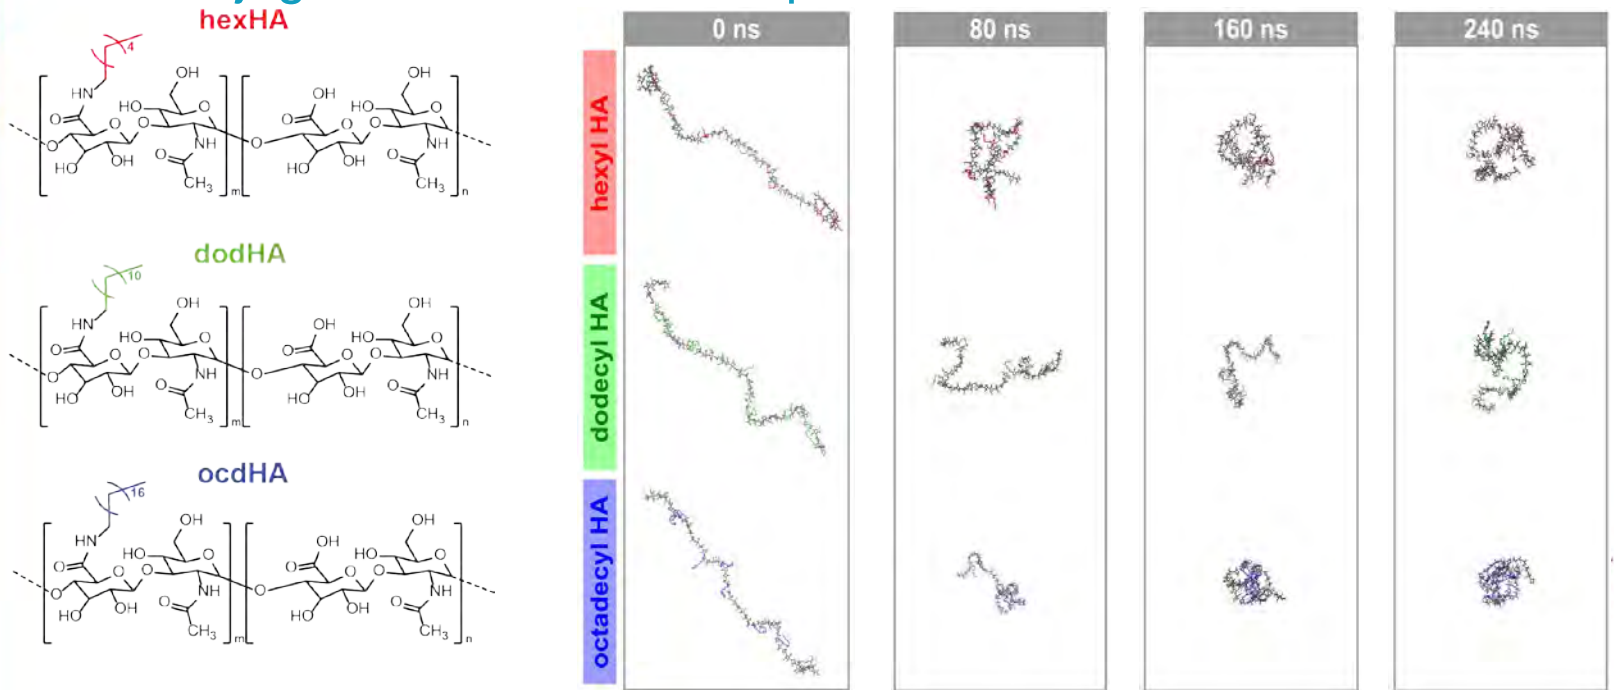

Pyrenyl-HA (pyHA)

DOAF DPAF

# Learning simulations

As an experimentalist, I had to learn everything

- My first simulations were of very simple polymer conjugates to learn how to perform simulations

# New Polymers

## Looking at aromatic substituents

- We increased the “library” of polymer models we use to include aromatic compounds

# New Models

## Moving to multi-polymer systems

- Systems were simulated containing multiple polymer strands to observe self-assembly

# Deeper-level measurement

## Using dyes to probe the internal environment

- Fluorescent dyes can reveal information on their immediate environment

Parent dye to provide reference response

Shielded carbonyl group to decrease influence of specific interactions on ESIPT

Long alkyl chains to enhance partitioning into hydrophobic part of the nanoparticle

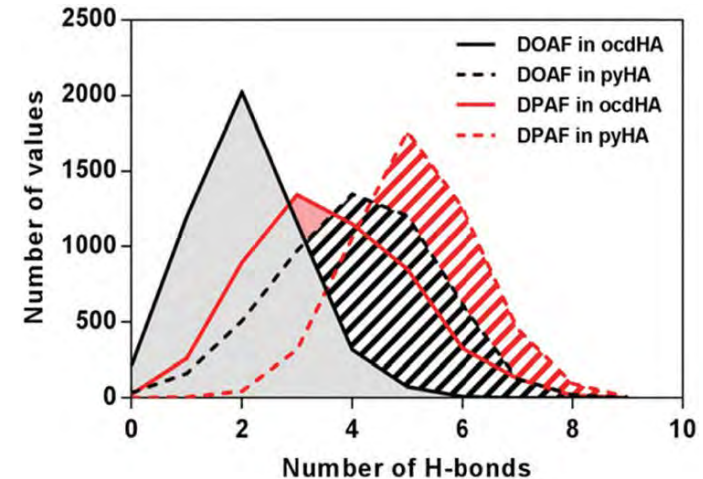

Additional phenyl rings to enhance  $\pi$ - $\pi$  stacking interactions

# Simulating Dye-Polymer Systems

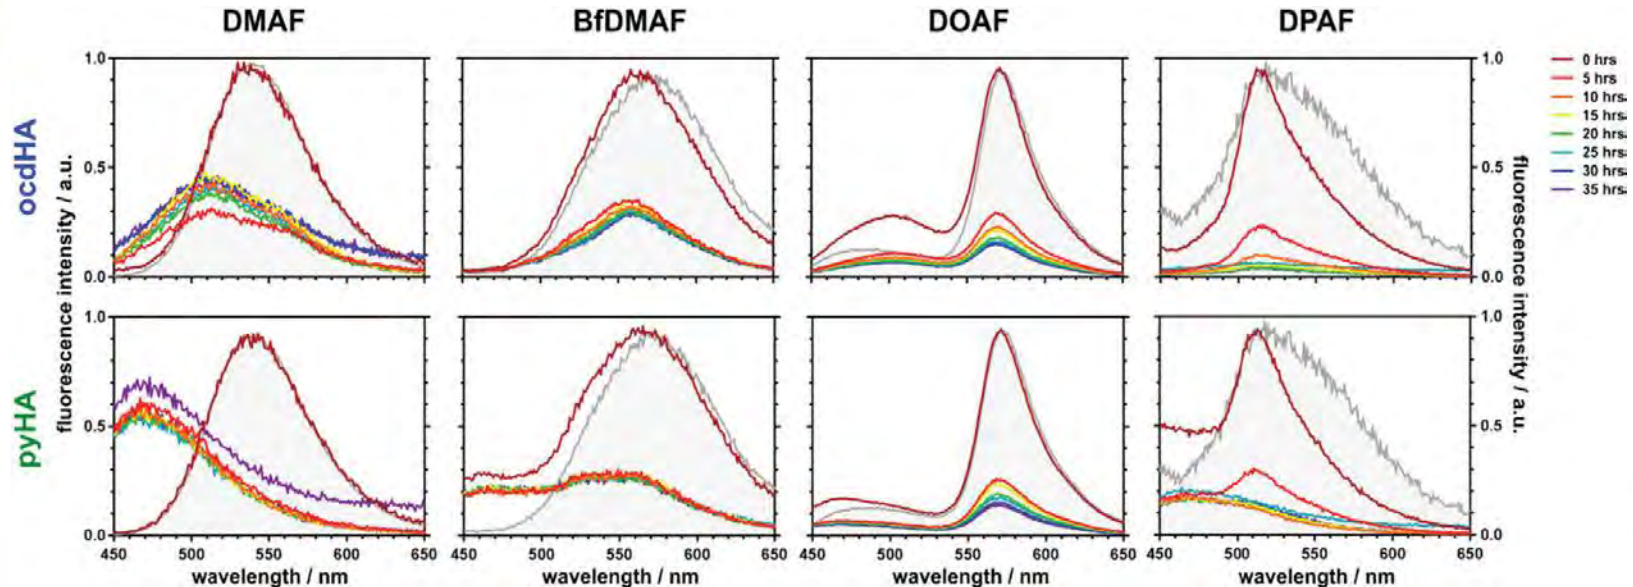

- We can measure interactions between dyes and polymers to explain experimental observations
- Aromatic vs. Aliphatic interactions

# Experimental Analysis

## Fluorescence spectroscopy to validate simulations

- We can perform spectroscopic measurements to gain more information on self-assembly

# Back to the original problem

How to improve the contrast obtained from polymer conjugates?

- Moving to different polymers to improve imaging efficacy

# Future Work

## Generalization and abstraction

- HA is not a suitable model polymer.
- Widespread applicability to the nanomedicine field is necessary for real impact.

### Poly(oxazoline)

### Poly(oxazine)

# Conclusions

- Simulations show promise in helping to inform the search for better formulations
- Quantitative methods afforded through molecular dynamics and similar methods may help to define what is a “good” formulation
- Using simulations in attempt to improve the formulation and original problem in polymeric contrast agents
